soil mechanics solved problems

Soil mechanics is a fundamental branch of geotechnical engineering that deals with the behavior of soil materials under various loadings and environmental conditions. The discipline involves understanding soil properties, designing foundations, retaining structures, and assessing stability of slopes. To master these concepts, solving practical problems is essential. These solved problems not only reinforce theoretical knowledge but also develop problem-solving skills critical for real-world geotechnical applications. In this article, we delve into a comprehensive collection of soil mechanics solved problems, covering key topics such as shear strength, bearing capacity, slope stability, consolidation, and more. These examples serve as valuable references for students, engineers, and professionals aiming to strengthen their understanding of soil mechanics concepts.

Basic Concepts and Shear Strength of Soils

Problem 1: Determining Shear Strength Parameters from Triaxial Test Data

Problem Statement:

A remolded clay sample subjected to a consolidated undrained (CU) triaxial test shows the following data:

- Axial stress at failure, $\sigma_1 = 150$ kPa
- Cell pressure, $\sigma_3 = 50$ kPa

Determine the cohesion (c) and the angle of internal friction (ϕ) of the soil.

Solution:

In a CU triaxial test, the shear strength parameters can be calculated using the Mohr-Coulomb failure criterion:

$$\tau = c + \sigma' \tan \phi$$

Where:

- τ = shear stress at failure
- σ' = effective normal stress at failure

Since the test is consolidated undrained, the pore pressure is assumed to be zero for simplicity in this problem or considered to be accounted for in the data.

The principal stresses are:

$$\sigma_1 = \text{axial stress}$$

$$\sigma_3 = \text{confining pressure}$$

The maximum shear stress at failure:

$$\tau_{\max} = \frac{\sigma_1 - \sigma_3}{2} = \frac{150 - 50}{2} = 50 \text{ kPa}$$

The mean normal stress at failure:

$$\sigma_m = \frac{\sigma_1 + \sigma_3}{2} = \frac{150 + 50}{2} = 100 \text{ kPa}$$

The Mohr's circle at failure passes through points:

- Normal stress: $(\sigma_m \pm \tau_{\max})$
- Shear stress: $(\pm \tau_{\max})$

Using the failure envelope:

$$\tau = c + \sigma' \tan \phi$$

Assuming the total stress parameters are applicable, the shear strength parameters are:

$$c = \text{intercept of failure envelope}$$

$$\phi = \text{angle of internal friction}$$

Alternatively, for simplicity, the parameters can be approximated as:

$$\tan \phi = \frac{\tau_{\max}}{\sigma_m} = \frac{50}{100} = 0.5 \implies \phi \approx 26.6^\circ$$

And the cohesion:

$$\tau_c = \tau_{\max} - \sigma_m \tan \phi = 50 - 100 \times 0.5 = 50 - 50 = 0, \text{ kPa}$$

Answer:

- Cohesion, $c = 0$ kPa
- Internal friction angle, $\phi = 26.6^\circ$

Problem 2: Shear Strength of Cohesionless Soil (Sand)

Problem Statement:

A clean, dry sand has a friction angle of 30° . Determine the shear strength at a normal stress of 100 kPa.

Solution:

Using the Mohr-Coulomb criterion for cohesionless soils:

$$\tau = \sigma' \tan \phi$$

Given:

- $\phi = 30^\circ$
- $\sigma' = 100, \text{ kPa}$

Calculate shear strength:

$$\tau = 100 \times \tan 30^\circ = 100 \times 0.577 = 57.7, \text{ kPa}$$

Answer:

Shear strength, $\tau \approx 57.7, \text{ kPa}$

Bearing Capacity of Foundations

Problem 3: Ultimate Bearing Capacity of a Square Foundation

Problem Statement:

A square footing of size 2 m x 2 m is founded on sandy soil with a cohesion $c = 0$ kPa, internal friction angle $\phi = 30^\circ$, and unit weight $\gamma = 18$ kN/m³. The depth of the foundation is 1 m. Determine the ultimate bearing capacity.

Solution:

Using Terzaghi's bearing capacity equation for shallow foundations:

$$q_u = c N_c + q N_q + 0.5 \gamma B N_\gamma$$

Where:

- $(q = \text{overburden pressure}) = \gamma D_f = 18 \times 1 = 18$, (kPa)
- $(B = 2)$, (m)
- (N_c, N_q, N_γ) are bearing capacity factors for $\phi = 30^\circ$.

From standard tables:

- $(N_c \approx 30.1)$
- $(N_q \approx 17.9)$
- $(N_\gamma \approx 19.7)$

Calculations:

$$\begin{aligned} q_u &= 0 \times 30.1 + 18 \times 17.9 + 0.5 \times 18 \times 2 \times 19.7 \\ &= 0 + 322.2 + 0.5 \times 18 \times 2 \times 19.7 \\ &= 322.2 + 0.5 \times 18 \times 39.4 \\ &= 322.2 + 0.5 \times 709.2 \\ &= 322.2 + 354.6 \\ &= 676.8, \text{ (kPa)} \end{aligned}$$

\end{aligned}

\]

Answer:

The ultimate bearing capacity $(q_u \approx 677, \text{kPa})$

Slope Stability Analysis

Problem 4: Factor of Safety for a Sloped Embankment

Problem Statement:

An embankment 10 m high with a slope of 1:2 (vertical:horizontal) is constructed on cohesive soil with $c = 20 \text{ kPa}$, $\phi = 20^\circ$, and $\gamma = 18 \text{ kN/m}^3$. Determine the factor of safety against sliding using the Bishop's simplified method.

Solution:

First, compute the weight of the slope:

$$[W = \frac{1}{2} \times \text{base} \times \text{height} \times \gamma]$$

For a slope of 1:2, base length $(b = 10 \times 2 = 20, \text{m})$.

Area of the slope surface:

$$[A = \frac{1}{2} \times b \times \text{height} = 0.5 \times 20 \times 10 = 100, \text{m}^2]$$

Weight:

$$[W = A \times \gamma = 100 \times 18 = 1800, \text{kN}]$$

Assuming the slip surface is a circular arc, the method involves calculating the shear strength along the slip surface and the component of weight acting downslope.

Given the complexity, a simplified approach yields the factor of safety (FoS):

$$[\text{FoS} = \frac{\text{Resisting forces}}{\text{Driving forces}}]$$

Using the simplified method formula:

$$FoS = \frac{c \times L + (W \times \cos \theta - u \times A) \times \tan \phi}{W \times \sin \theta}$$

Where:

- θ is the slope angle = $\arctan(1/2) \approx 26.6^\circ$
- L is the length of the slip surface, approximated as the arc length; for simplicity, assume the resisting shear strength is proportional to $(c \times \text{perimeter})$

For an approximate evaluation, the factor of safety is often found to be around 1.5 to 2 for such slopes, indicating stability.

Answer:

Estimated factor of safety ? 1.8, indicating the slope is stable with adequate safety margin.

Consolidation and Settlement Problems

Problem 5: Consolidation Settlement Calculation

Problem Statement:

A clay layer 4 m thick is loaded with a pressure increase of 100 kPa. The coefficient of consolidation (C_v) is 0.0002 m²/day, and the compression index (C_c) is 0.2. Determine the primary consolidation settlement.

Solution:

The primary consolidation settlement (S) is given

Illustrative Solved Problems in Soil Mechanics

To illustrate these principles, consider a few detailed problems across various topics:

Problem 1: Determining the Maximum Dry Density and Optimum Moisture Content

Scenario: A Proctor compaction test is performed on a soil sample. The results show that at a moisture content of 12%, the dry density reaches its maximum value of 1.75 g/cm^3 .

Solution Approach:

- Recognize this as a typical compaction problem.
- Use the data directly: maximum dry density = 1.75 g/cm³ at optimum moisture content = 12%.
- To find wet density, use:

$$\left[\right.$$

$$\text{Wet Density} = \frac{\text{Dry Density}}{1 - \frac{\text{Moisture Content}}{100}}$$

$$\left. \right]$$

- Calculation:

$$\left[\right.$$

$$\text{Wet Density} = \frac{1.75}{1 - 0.12} = \frac{1.75}{0.88} \approx 1.989, \text{ g/cm}^3$$

$$\left. \right]$$
Key Learning:

- Application of basic formulas.
- Understanding the relationship between dry and wet densities.

Problem 2: Calculating Coefficient of Permeability from Laboratory Data

Scenario: A soil sample exhibits a flow rate of 2 cm³/min through a 10 cm long and 5 cm diameter specimen, with a hydraulic gradient of 10. Determine the coefficient of permeability.

Solution Approach:

- Convert data into SI units:
- Cross-sectional area:

\[

$$A = \frac{\pi}{4} \times d^2 = \frac{\pi}{4} \times 5^2 \approx 19.635 \text{ cm}^2$$

\]

- Discharge per unit area:

\[

$$q = \frac{\text{Flow rate}}{A} = \frac{2 \text{ cm}^3/\text{min}}{19.635 \text{ cm}^2} \approx 0.102 \text{ cm/min}$$

\]

- Darcy's law:

\[

$$q = k \times i$$

\]

where i is the hydraulic gradient.

- Rearranged:

\[

$$k = \frac{q}{i} = \frac{0.102}{10} = 0.0102 \text{ cm/min}$$

\]

Result: The coefficient of permeability $k \approx 0.0102 \text{ cm/min}$.

Problem 3: Shear Strength of Cohesive Soil Using Mohr-Coulomb Criterion

Scenario: A clay soil sample shows a cohesion $c = 25 \text{ kPa}$ and an internal friction angle ϕ

$\phi = 20^\circ$). The normal stress applied during a shear test is 100 kPa. Calculate the shear strength.

Solution Approach:

- Use the Mohr-Coulomb equation:

[

$$\tau = c + \sigma \tan \phi$$

]

- Calculation:

[

$$\tau = 25 + 100 \times \tan(20^\circ) \approx 25 + 100 \times 0.3640 = 25 + 36.4 = 61.4, \text{ kPa}$$

]

Conclusion: The shear strength under these conditions is approximately 61.4 kPa.

- Seepage Analysis with Flow Nets: Constructing flow nets to analyze seepage pressures and potential piping.

Solving these problems often involves iterative methods, numerical analysis, and software tools like GeoStudio or PLAXIS.

Tips for Effective Problem Solving in Soil Mechanics

Question What are the common methods used to analyze slope stability in soil mechanics? Common methods include limit equilibrium methods like Bishop's and Janbu's methods, the method of slices, and numerical methods such as finite element analysis. These approaches help assess potential failure surfaces and factor of safety for slopes. How do you determine the bearing capacity of a shallow foundation in a solved problem? To determine the bearing capacity, you typically apply Terzaghi's bearing capacity equation, considering factors like soil cohesion, unit weight, and footing size. Solved problems often involve calculating the ultimate bearing capacity and applying a factor of safety to find the allowable bearing pressure. What is the significance of the Atterberg limits in soil mechanics problems? Atterberg limits help classify soil plasticity and consistency, which are crucial for understanding soil behavior under load. Solved problems often involve determining the liquid limit, plastic limit, and plasticity index to predict soil stability and compaction characteristics. How is consolidation settlement calculated in solved soil mechanics problems? Consolidation settlement is calculated using Terzaghi's one-dimensional consolidation theory, which involves determining the compression index, initial void ratio, and applied load. The problem typically provides soil parameters to compute the expected settlement over time. What are the typical steps involved in solving a problem related to undrained shear strength in clay soils? The steps include identifying the soil type, referencing laboratory test results for undrained shear strength (C_u), and applying appropriate shear failure criteria. The solution often involves calculating the factor of safety or predicting failure stress based on given parameters. How can one assess the

liquefaction potential of saturated sandy soils through solved problems? Assessment involves calculating the cyclic stress ratio (CSR) and comparing it with the soil's cyclic resistance ratio (CRR), often derived from standard penetration test (SPT) or cone penetration test (CPT) data. Solved problems typically guide through these calculations to determine liquefaction risk during earthquakes.

A seguir, exploraremos os principais pontos deste capítulo com exemplos resolvidos para melhor compreensão.

Conceitos Fundamentais do Capítulo 6

1. Tensão Normal e Tensão de Cisalhamento

- **Tensão Normal (?)**: força que atua perpendicularmente à seção transversal do elemento estrutural, causando alongamento ou encurtamento.
- **Tensão de Cisalhamento (?)**: força que atua paralelamente à seção, provocando deslizamento entre partículas.

2. Diagramas de Esforços

- Representações gráficas que mostram como os esforços internos variam ao longo do comprimento de uma estrutura.
- Incluem diagramas de tensão normal, cisalhamento e momento fletor.

3. Critérios de Resistência

- Condições que determinam se uma estrutura suporta as cargas sem atingir limites de ruptura ou deformação excessiva.
- Exemplos: critério de máxima tensão, critério de von Mises.

Resolução de Exercícios do Capítulo 6

A prática de exercícios é essencial para fixar os conceitos. A seguir, apresentamos passos gerais para resolver exercícios de resistência dos materiais do capítulo 6, acompanhados de exemplos resolvidos.

Passos para Resolver Exercícios

- **Leitura atenta do enunciado:** identificar todas as informações disponíveis como cargas, dimensões, suportes e condições de contorno.
- **Desenho do esquema:** fazer um diagrama claro do problema, incluindo as forças e esforços internos.
- **Determinação dos esforços internos:** calcular esforços cortantes, momentos fletores e tensões neste ponto específico.
- **Aplicação das fórmulas de tensões:** usar as equações de tensão normal e cisalhamento para encontrar valores numéricos.
- **Verificação dos critérios de resistência:** comparar as tensões com os limites admissíveis.
- **Conclusão:** interpretar os resultados, verificar a segurança ou necessidade de reforço.

Exemplo Resolvido

Problema: Uma viga simply supported (apoios simples) de comprimento 4 metros está submetida a uma carga concentrada de 10 kN no centro. Determine a tensão máxima na seção central e verifique se a viga suporta a carga, considerando um momento de resistência de 150 MPa.

- **Esquema do problema:** Representação da viga com uma carga no centro e apoios nas extremidades.
- **Calculando o momento fletor máximo:**
 - $M_{max} = (P L) / 4 = (10 \text{ kN } 4 \text{ m}) / 4 = 10 \text{ kN } 1 \text{ m} = 10 \text{ kN}\cdot\text{m}$
- **Calculando a tensão normal máxima:**
 - Seja A seção transversal com área $A = b h$ (exemplo: $0,1 \text{ m } 0,2 \text{ m} = 0,02 \text{ m}^2$)
 - $\sigma_{max} = M_{max} c / I$, onde c é a distância do centro da seção até a fibra mais afastada, e I é o momento de inércia da seção.
- **Para uma seção retangular:**
 - $I = (b h^3) / 12 = (0,1 \text{ m } 0,2^3) / 12 = 6,67 \cdot 10^{-6} \text{ m}^4$
 - $c = h/2 = 0,1 \text{ m}$
 - $\sigma_{max} = (M_{max} c) / I = (10,000 \text{ N}\cdot\text{m } 0,1 \text{ m}) / 6,67 \cdot 10^{-6} \text{ m}^4 = 150 \text{ MPa}$
- **Verificação da resistência:** Como o limite de resistência é 150 MPa, a viga está no limite da resistência. Recomenda-se uma análise mais detalhada ou reforço.

Principais Dicas para Estudo de Exercícios do Capítulo 6

- **Familiarize-se com as fórmulas:** Conheça bem as equações de tensão normal, cisalhamento e momento fletor.

Resolução de Exercícios: Técnicas e Estratégias

Para abordar os exercícios do capítulo 6 de forma eficiente, é importante dominar algumas técnicas de resolução que facilitam a compreensão e agilizam o processo.

1. Compreensão do Enunciado

Antes de iniciar a resolução, leia atentamente o enunciado, identificando:

- Tipo de carga aplicada (axial, transversal, momento fletor).
- Geometria do elemento.
- Condições de contorno e apoios.
- Objetivo do problema (calcular tensões, deformações, máximos, mínimos).

2. Esquematização do Problema

- Desenho esquemático da estrutura ou elemento.
- Marcação das forças, momentos e pontos de interesse.
- Definição do sistema de coordenadas.

3. Cálculo das Tensões

- Utilizar fórmulas básicas para tensões normais ($\sigma = \frac{P}{A}$) ou cisalhamento ($\tau = \frac{V}{A}$), dependendo do tipo de carregamento.
- Para estados de tensão complexos, aplicar o método de superposição ou diagramas de Mohr.

4. Análise de Estados de Tensão

- Determinar tensões principais através da resolução de equações de tensões principais.
- Construir o círculo de Mohr para visualizar o estado de tensão em diferentes planos.

5. Determinação de Deformações

- Aplicar a Lei de Hooke: $\epsilon = \frac{\sigma}{E}$ para deformações normais.
- Considerar o efeito do coeficiente de Poisson ao calcular deformações transversais.

6. Verificação de Critérios de Resistência

- Comparar tensões calculadas com os limites admissíveis.
- Avaliar fatores de segurança.

Exemplos de Exercícios Resolvidos do Capítulo 6

Para ilustrar a aplicação prática, analisaremos um exercício típico e suas etapas de resolução.

Exercício 1: Cálculo de Tensões em uma Viga Axialmente Carregada

Enunciado: Uma viga de seção transversal retangular, de área $(A = 100\text{ cm}^2)$, é submetida a uma carga axial de $(P = 50\text{ kN})$. Determine a tensão normal na seção e avalie se o elemento suporta a carga considerando um limite de resistência de $(\sigma_{\text{admissível}} = 250\text{ MPa})$.

Resolução:

- Passo 1: Converter unidades para consistência:

$$(A = 100\text{ cm}^2 = 1 \times 10^{-2}\text{ m}^2)$$

- Passo 2: Calcular a tensão normal:

$$(\sigma = \frac{P}{A} = \frac{50 \times 10^3\text{ N}}{1 \times 10^{-2}\text{ m}^2} = 5 \times 10^6\text{ Pa} = 5\text{ MPa})$$

- Passo 3: Comparar com o limite de resistência:

Como 5 MPa

Este exercício demonstra a aplicação direta da fórmula de tensão normal, um conceito fundamental no capítulo.
