- Create a new Java class named HelloWorld.
- Write the following code inside the class:

```
public class HelloWorld {
```

```
    public static void main(String[] args) {
```

```
        System.out.println("Hello, World!");
```

```
    }
```

```
}
```

- Save the file.
- Compile and run the program. In most IDEs, this can be done with a single click or keyboard shortcut.

Understanding the Code

- **public class HelloWorld:** Defines a class named HelloWorld, which is the blueprint for your program.
- **public static void main(String[] args):** The main method, the entry point of any Java application.
- **System.out.println("Hello, World!");**: Prints the message to the console.

Core Concepts of Java Programming for Beginners

To build a solid foundation, it's essential to understand key concepts that form the basis of Java programming.

Variables and Data Types

Variables store data that your program can manipulate. Java has several data types:

- **int:** Integer numbers (e.g., 10, -5)
- **double:** Floating-point numbers (e.g., 3.14, -0.001)
- **char:** Single characters (e.g., 'A', 'z')
- **boolean:** true or false values
- **String:** Text strings (e.g., "Java programming")

Example:

```
int age = 25;
```

```
double price = 19.99;
```

```
char grade = 'A';
```

```
boolean isJavaFun = true;
```

```
String message = "Hello, Java!";
```

Control Structures

Control structures determine the flow of your program.

- **If-else statements:** Make decisions based on conditions.
- **Loops:** Repeat actions using for or while loops.

Example of an if-else statement:

```
if (age >= 18) {  
  
    System.out.println("Adult");  
  
} else {  
  
    System.out.println("Minor");  
  
}
```

Example of a for loop:

```
for (int i = 0; i  
    System.out.println("Count: " + i);  
  
}
```

Methods and Functions

Methods are blocks of code designed to perform specific tasks, promoting code reusability.

Example:

```
public static int add(int a, int b) {  
  
    return a + b;  
  
}
```

You can call this method from your main method:

```
int sum = add(5, 10);  
  
System.out.println("Sum: " + sum);
```

Object-Oriented Programming (OOP) Basics

Java is inherently object-oriented, meaning it revolves around objects and classes.

Classes and Objects

- **Class:** A blueprint for creating objects; defines properties and behaviors.
- **Object:** An instance of a class.

Example:

```
public class Car {  
  
    String model;  
  
    int year;  
  
    void drive() {  
  
        System.out.println("The car is driving");  
  
    }  
  
}  
  
// Creating an object  
  
Car myCar = new Car();  
  
myCar.model = "Toyota";  
  
myCar.year = 2020;  
  
myCar.drive();
```

Encapsulation and Inheritance

- **Encapsulation:** Hiding internal details and protecting data.
- **Inheritance:** Creating new classes based on existing ones to promote code reuse.

Best Practices for Beginning Java Developers

- Write clean, readable code with meaningful variable names.
- Comment your code to explain complex sections.

```
```python  

print("Hello, World!")

```
```

- Save the File:
 - Name it `hello.py` or any preferred name.

- Run the Program:
- Tap the run button or select 'Run' from the menu.
- See the Output:
- Your screen should display: `Hello, World!`

Understanding the Code

- `print()` is a built-in Python function that outputs text to the console.
- The string `"Hello, World!"` is what appears on the screen.

Basic Concepts in Python for Beginners

Before progressing to more complex programs, it's important to understand some fundamental concepts.

Variables and Data Types

Variables store information that can be used and manipulated throughout your program.

Common Data Types:

- Integers: Whole numbers (e.g., 1, 42)
- Floats: Decimal numbers (e.g., 3.14, 0.001)
- Strings: Text data (e.g., "Python", 'Hello')
- Booleans: True or False values

Example:

```
python
```

```
name = "Alice"
```

```
age = 25
```

```
height = 5.6
```

```
is_student = True
```

```
...
```

Operators and Expressions

Operators perform operations on variables and values:

| Operator | Description | Example |
|----------|-------------|---------|
|----------|-------------|---------|

| Operator | Description | Example |
|----------|-------------|---------|
|----------|-------------|---------|

| | | |
|---|----------|----------------------|
| + | Addition | <code>`a + b`</code> |
|---|----------|----------------------|

| | | |
|---|-------------|----------------------|
| - | Subtraction | <code>`a - b`</code> |
|---|-------------|----------------------|

| | | |
|---|----------------|----------------------|
| * | Multiplication | <code>`a * b`</code> |
|---|----------------|----------------------|

| | | |
|---|----------|----------------------|
| / | Division | <code>`a / b`</code> |
|---|----------|----------------------|

| | | |
|---|---------|----------------------|
| % | Modulus | <code>`a % b`</code> |
|---|---------|----------------------|

Control Structures

Control flow determines the order in which code executes.

Conditional Statements:

```
```python
```

```
if age >= 18:
```

```
 print("Adult")
```

```
else:
```

```
 print("Minor")
```

```
...
```

Loops:

```
```python
```

```
for i in range(5):
```

```
    print(i)
```

```
```
```

## Developing Your First Projects on a Tablet

Once familiar with basic syntax, you can start creating simple projects to reinforce your learning.

### Number Guessing Game

Objective: Write a program that randomly selects a number, and the user tries to guess it.

Sample Implementation:

```
```python
```

```
import random
```

```
secret_number = random.randint(1, 100)
```

```
print("Guess the number between 1 and 100!")
```

```
while True:
```

```
    guess = int(input("Your guess: "))
```

```
    if guess == secret_number:
```

```
        print("Congratulations! You guessed it!")
```

```
        break
```

```
    elif guess
```

```
        print("Too low. Try again.")
```

else:

```
print("Too high. Try again.")
```

```
...
```

Note: Depending on your app, `input()` may require a different approach, such as using text input fields.

Simple Calculator

Create a program that performs basic arithmetic:

```
```python
```

```
num1 = float(input("Enter first number: "))
```

```
operator = input("Enter operator (+, -, , /): ")
```

```
num2 = float(input("Enter second number: "))
```

```
if operator == '+':
```

```
 result = num1 + num2
```

```
elif operator == '-':
```

```
 result = num1 - num2
```

```
elif operator == "*":
```

```
 result = num1 * num2
```

```
elif operator == '/':
```

```
 if num2 != 0:
```

```
 result = num1 / num2
```

```
else:
```

```
result = "Error: Division by zero!"
```

```
else:
```

```
result = "Invalid operator."
```

```
print("Result:", result)
```

```
```
```
